I, the undersigned, being an officer duly authorised in accordance with Section 74(1) and (4) of the Deregulation & Contracting Out Act 1994, to sign and issue certificates on behalf of the Comptroller-General, hereby certify that annexed hereto is a true copy of the documents as originally filed in connection with the patent application identified therein.

U J R U

In accordance with the Patents (Companies Re-registration) Rules 1982, if a company named in this certificate and any accompanying documents has re-registered under the Companies Act 1980 with the same name as that with which it was registered immediately before re-registration save for the substitution as, or inclusion as, the last part of the name of the words "public limited company" or their equivalents in Welsh, references to the name of the company in this certificate and any accompanying documents shall be treated as references to the name with which it is so re-registered.

In accordance with the rules, the words "public limited company" may be replaced by p.l.c., plc, P.L.C. or PLC.

Re-registration under the Companies Act does not constitute a new legal entity but merely subjects the company to certain additional company law rules.

Compound Lens Arrangement for use in Lens Arrays

5 The present invention relates to a compound lens arrangement for use in arrays of lenses and in particular to a compound lens arrangement for use in arrays of lenses or for use in projectors arranged in an array in multi-perspective autostereo projection systems.

10 In known multi-perspective autostereo projection systems the images from a plurality of projectors which show different perspective views of an object are projected onto a direction selective projection screen, such as a field lens. Such screens have the characteristic of re-forming the array of images of the projector lens exit pupils in a "viewer space" so
15 that each viewer of the screen sees a stereo image pair and accordingly sees a three dimensional image. Thus, if a viewer horizontally crosses between adjacent images, the three dimensional image changes discontinuously or "flips". A problem with this type of display is that the images seen by the viewer are separated by dark regions associated
20 with gaps between the projection lenses.

In a paper entitled "Autostereoscopic 3D-imaging by front and rear projection and on flat panel displays" by R Borner which was published in "Displays", Volume 14, Number 1, 1993 by Butterworth-Heinemann
25 Ltd, this problem is tackled by overlapping the exit pupils of the projector lenses by using at least two vertically spaced layers of projectors lenses horizontally off-set with respect to each other. In this way the axis of an exit pupil of a projector lens in a first layer will lie in a horizontal plane located between the axes of the exit pupils of two adjacent projector
30 lenses in a second layer. The images of the projector lens exit pupils from different layers can be overlapped in the "viewer space" using lenticular screens in order to eradicate dark regions between the images

in the "viewer space". A similar approach is used in a paper entitled "An autostereoscopic real-time 3D display system" by G. Bader, E. Lueder and J. Fuhrmann published in Euro Display '96. The resulting display apparatus using such multi-layer arrangements can be overly complex
5 and the use of lenticular arrays to spread out the exit pupil image can affect the projected picture quality.

In a paper entitled "Multiperspective autostereoscopic display" by Gordon R. Little, Steven C. Gustafson and Vasiliki E. Nikolaou
10 published in SPIE Volume 2219 Cockpit Displays (1994), the problem of gaps between adjacent images in the "viewer space" is solved by using a pupil forming screen which comprises a Fresnel lens and a lenticular array to spread out each image in the "viewer space" to remove any gaps between adjacent images. This again has the disadvantage of
15 affecting the projected picture quality by reducing the resolution of the display.

The present invention aims to overcome at least some of the problems discussed above by providing a compound lens arrangement for use in
20 arrays of lenses which substantially eliminates the problem of dark spaces between images in the "viewer space" without requiring over-complex display arrangements and without reducing the resolution of the image seen by the viewer.

25 According to a first aspect of the present invention there is provided a compound lens arrangement for use in an array of such lens arrangements comprising at least two lens elements including a front lens element having a front lens surface which is the largest diameter lens surface in the compound lens arrangement, wherein the exit pupil
30 of the compound lens arrangement lies in the plane of and is bounded by the edge of said front lens surface. In such a compound lens arrangement the exit pupil lies at the front of the arrangement at the

largest diameter lens surface of the arrangement which means that in an array of such compound lens arrangements, adjacent abutting lens arrangements will have adjacent abutting exit pupils. Thus, there will be no gaps between the exit pupils of adjacent compound lens arrangements and so the present invention can be used to eliminate the problem of dark spaces between images in the "viewer space" in autostereo projection systems. The compound lens arrangement according to the present invention is of use in any application requiring the use of arrays of lenses with abutting exit pupils.

10

The aperture stop may be located within the front lens element of the compound lens. Preferably, the aperture stop of the lens lies in front of the lens element(s) of the compound lens arrangement other than the front lens element as this improves the symmetry of the lens arrangement about the aperture stop and helps to reduce coma, distortion and transverse colour in the compound lens. The aperture stop of the compound lens arrangement may lie in a plane which intersects the optical axis of the compound lens arrangement at the rear lens surface of the front lens element.

20

The front lens element may itself be a compound lens or alternatively could comprise a single lens. It is preferred that the rear lens surface of the front lens element is concave and further that the front lens surface of the front lens element is convex.

25

In a preferred arrangement the front lens element is the largest diameter lens element in the compound lens arrangement.

30

The first aspect of the present invention relates to a compound lens arrangement with its exit pupil located at its last (or front) surface with the edge of the exit pupil being the intersecting ring of the plane where the exit pupil is located and said last surface. The diameter of the exit

pupil defines the largest diameter of the compound lens arrangement and the radius of the exit pupil is larger than or equal to all the ray heights traced through the compound lens without vignetting. Thus, several such compound lenses can be arranged in an array so that their exit pupils abut so that there will be no dark zone when this compound lens array is used as the projection lens array in a multi-projector autostereoscopic display.

According to a second aspect of the present invention there is provided a projector for use in an array of such projectors comprising a compound lens arrangement according to the first aspect of the present invention. As discussed above such a projector can be used in an abutting array of such projectors in an autostereo projection system in order to eliminate gaps between images in the "viewing space" of the system.

According to a third aspect of the present invention there is provided an autostereo projection system comprising an array of projectors according to the second aspect of the present invention.

According to a fourth aspect of the present invention there is provided a method of designing a compound lens arrangement for use in an array of such lenses comprising the steps of;

defining the material of a front lens element of the compound lens arrangement, the diameter of a front lens surface of the front lens element, the radius of curvature of the front lens surface and a rear lens surface of the front lens element and defining the location of an exit pupil of the compound lens arrangement to be in the plane of and bounded by the edge of said front lens surface,

based on the above defined parameters, tracing the location and magnitude of an aperture stop of the compound lens arrangement by tracing the marginal rays through the front lens element using ray tracing means,

5

repeating the above steps until the marginal ray heights through the front lens element are highest at the exit pupil, and then fixing the above defined parameters,

10

defining the diameters of the remaining lens surfaces of the compound lens arrangement to be less than that of the front lens surface of the front lens element and defining the functionality of the compound lens arrangement.

15

using ray tracing means to design the remainder of the compound lens arrangement, in such a way that the remaining lens surfaces do not alter the relationship between the exit pupil and the marginal ray height through the front lens element defined above.

20

Preferably, the parameters defined in the first step of the method are only fixed when the diameter of the aperture stop is less than the diameter of the exit pupil.

25

This method can be used to design a compound lens arrangement according to the first aspect of the present invention and which will have the advantages associated with the first aspect of the present invention.

30

The term marginal ray is used generally to describe those rays which pass through the edge of an aperture stop or an entrance or exit pupil of a lens system. The marginal ray is that ray which is the highest (ie. moves furthest away from the optical axis) amongst the rays traced

through a lens system from an object point. In a compound lens according to the present invention the marginal rays will pass through the edge of the exit pupil, because the exit pupil is real.

- 5 Preferably, the step of defining the diameter of the front lens surface of the front lens element comprises the step of defining the diameter of the front lens element.

10 Preferably, the step of defining the functionality of the compound lens arrangement comprises the step of defining the compound lens as a finite conjugate lens with specified object and image distances as such a compound lens would be suitable for use in a projector of an autostereo projection system. Alternatively, the compound lens arrangement could be defined as a finite-infinite conjugate lens element.

15

For the purposes of the present invention the aperture stop shall be defined as the image of the exit pupil.

20

The present invention will now be described by way of example only with reference to the accompanying figures in which:

25

Figure 1a shows schematically a multi-perspective autostereo display system using a direction selective projection screen and an array of projectors each comprising a compound lens according to the present invention.

30

Figure 1b shows schematically a multi-perspective autostereo display system using a field lens and an array projectors each comprising a compound lens according to the present invention.

Figure 2 shows a first embodiment of a compound lens arrangement according to the present invention.

Figure 3 shows a plot of the modulation transfer function of the compound lens of Figure 2.

5 Figure 4 shows an upper portion of the front lens element of the compound lens of Figure 2.

Figure 5 shows a second embodiment of a compound lens arrangement according to the present invention.

10

Figure 6 shows a third embodiment of a compound lens arrangement according to the present invention.

15 Figure 7 shows the method steps involved in designing a compound lens arrangement according to the present invention.

Figures 1a and 1b show multi-perspective autostereo display systems in which three projectors (2,4,6) each project an image taken from a different perspective of an object or scene. Each projector (2,4,6) comprises a respective compound lens arrangement (12, 14, 16) in accordance with the present invention which is designed as described below so that the exit pupil of each lens coincides with the front surface of the lens and so that the front element of the lens has the largest diameter. This means that the exit pupils of the compound lenses (12,14,16) can be located adjacent each other so that they touch, thus eliminating any gaps between the exit pupils of adjacent projector lenses (12,14,16)

20

25

A direction selective projection screen (8a) in Figure 1a or a field lens (8b) in Figure 1b re-forms the images of the projector lens exit pupils in the viewer space to form images (22,24,26) and as can be seen from Figures 1a and 1b adjacent ones of these images also touch each other

30

to eliminate gaps between adjacent images in the "viewer space". A viewer (10) located in a first viewing position sees image (22) from projector (2) in one eye and image (24) from projector (4) showing the same object or scene from a different perspective in the other eye so that the viewer sees a three dimensional image from a first perspective. If the viewer were to move his or her head to the left in Figure 1a or upwards in Figure 1b to a second viewing position so that he or she sees image (24) from projector (4) in one eye and image (26) from projector (6) in the other eye so that he or she would see a three dimensional image of the object or scene from a second perspective. In moving from the first to the second viewing position the three dimensional image viewed would flip between the first and the second perspective, but there would be no dark spaces between the different images viewed by the viewer (10) because there is no gap between adjacent images (22) and (24) or adjacent images (24) and (26).

Accordingly, it can be seen that the compound lens arrangement according to the present invention enables the projectors (2,4,6) to abut so that there is no drop off in illumination between viewing zones (22,24,26). This provides a simplified, single layer projector arrangement without prejudicing the resolution of the images (22,24,26) in the "viewing space".

In order to be able to locate compound lenses in an array so that their edges touch it is not the aperture stop of the lenses which must abut, but the exit pupil of the lenses. The exit pupil is generally defined as an image of the aperture stop as seen from the image side (or in the image space) of the lens. In conventional lens designs the exit pupil is a virtual image formed deep inside the lens, close enough to the aperture stop that there is little difference between the two. However, if the lens elements in the compound lens between the aperture stop and the exit pupil are appropriately chosen it is possible for the edges of the exit

pupil to coincide with the edges of the front surface of the compound lens. If this front surface of the compound lens is the largest diameter part of the compound lens, even though the position of the aperture stop remains within the body of the lens, the exit pupil of adjacent lenses can
5 be made to abut. It should be noted that with this compound lens arrangement there are lens elements to both sides of the aperture stop and so lens elements to one side of the aperture stop are able to compensate for aberrations to the other side of the aperture stop within the compound lens. It then remains to ensure that the lenses behind
10 the exit pupil all have diameters smaller than the exit pupil in order physically to allow the exit pupils of adjacent lens arrangements to abut.

Figure 2 shows a first embodiment of a compound lens (30) designed in accordance with the present invention. The lens is designed using a
15 lens design software Code V available from Optical Research Associates, 3-80 East Foothill Boulevard, Pasadena, California 91107, USA which uses ray tracing algorithms.

The Figure 2 compound lens (30) comprises four lens elements
20 (32,34,36,38) and has an effective focal length of 25mm, an F-number of 2.5 and a field angle of 20 degrees. The aperture stop, is located in the plane (40) shown in dotted lines (ie. in the plane perpendicular to the optical axis (42) of the lens (30) at the point where the principle ray (44) crosses the axis (42)). It can be seen that the lens (30) is not symmetric
25 about the aperture stop and so the lens (30) has a high order coma sufficient to get an aberration of 0.05mm at a field angle of 10 degrees. Despite this the lens (30) is approximately achromatic and its modulation transfer function at 30 cycles/mm is at least 0.5 for any field point (See Figure 3).

30

In Figure 2 there are four lens elements (32,34,36,38) comprising eight lens surfaces (a to h). The lens element (32) is the front lens element

and faces towards the screen (8a) or field lens (8b) in the arrangements of Figures 1a and 1b respectively. The front lens element (32) is made of F5 SCHOTT glass and has a front surface (a) with a radius of curvature of 10.00mm and a rear surface (b) with a radius of curvature
5 36.89mm and a thickness along its optical axis (42) of 2.00mm. Abutting the rear surface (b) of the front lens element (32) is a second lens element (34). The second lens element (34) is made of PSK53A SCHOTT glass and has a front surface (c) with a radius of curvature 10.14mm and a rear surface (d) with a radius of curvature -22.06mm
10 and a thickness along its optical axis (42) of 5.10mm. It should be noted that the principle ray (44) crosses the optical axis (42) of the compound lens (30) at the interface between the rear surface (b) of the front lens element (32) and the front surface (c) of the second lens element (34) and so the aperture stop of the compound lens (30) lies in the plane
15 (40) perpendicular to the optical axis (42) and which intersects the optical axis (42) at said interface. A third lens element (36) is located behind the rear surface (d) of the second lens element (34) at a distance along the optical axis (42) of the lens elements of 0.10mm. The third lens element is made of SF4 SCHOTT glass and has a front
20 surface (e) with a radius of curvature -18.36mm and a rear surface (f) with a radius of curvature of 5.79mm and a thickness along its optical axis (42) of 0.55mm. A rear lens element (38) made of SF4 SCOTT glass is located behind the rear surface (f) of the third lens element (36) at a distance along the optical axis (42) of the lens elements of 6.05mm.
25 The rear lens element (38) has a front surface (g) with a radius of curvature of 14.63mm and a rear surface (h) with a radius of curvature of 62.17mm and a thickness along its optical axis (42) of 6.00mm.

The exit pupil of the compound lens (30) is located in the plane (46)
30 shown in full lines in Figure 2 and is bounded by the circumference of the front surface (a) of the front lens element (32). This can be seen more clearly in Figure 4 which shows an upper portion of the front lens

element (32) with the aperture stop, which is a virtual image of the exit pupil lying in the plane (40). In the absence of the front lens element (32) the marginal rays from all three field points (44,48,50) would intersect at point (52) as shown by the ray construction in dotted lines.

5 Point (52) defines the upper edge of the of the aperture stop of the compound lens (30) of Figure 2. The addition of the front lens element (32) refracts the marginal rays at its rear surface (b) so that they intersect at point (54) which is the upper edge of the exit pupil of the compound lens (46). The exit pupil is the image of the aperture stop at
 10 the image side of the aperture stop, and so lies in a plane (46) perpendicular to the optical axis (42) and is bounded by intersection points (54). The front lens element (32) is designed so that the intersection points (54) lie at the circumference of the front surface (a) of the front lens element (32). The compound lens (30) is designed so that
 15 the circumference of the front surface (a) of the front lens element (32) is greater than any other circumference of a lens element used in the compound lens. In this way adjacent compound lenses (30) can be placed together in an array with their exit pupils abutting.

20 The aperture stop is a virtual image of the exit pupil. The height of the aperture stop is the distance from the point (52) to the optical axis (42) and the height of the marginal ray at the exit pupil is the distance from the point (54) to the optical axis (42). It can be seen that the marginal ray heights all the way through the front lens element (32) are less than
 25 the marginal ray height at the exit pupil.

It should be noted that the front lens element (32) could be a compound lens element comprising more than one lens element.

30 The compound lens (30) is designed as indicated above using the Code V software package. It is designed in accordance with the following method, the steps of which are shown in Figure 7:

1. Define the material of the front lens (32), which in the Figure 2 example is F5 SCHOTT optical glass (Box 80, Figure 7).

5

2. Define the diameter of the front lens element (32) (Box 82).

10

3. Define the radius of curvature of the front surface (a) and the rear surface (b) of the front lens element (32) (Box 84).

15

4. Define the location of the exit pupil to be in the plane perpendicular to the optical axis of the compound lens which intersects the edge of the front surface (a) of the front lens (32) and define the exit pupil to be bounded by the circumference of the front surface (a) of the front lens (32) (Box 86).

20

5. Use the ray tracing Code V software to find the diameter and location of the aperture stop (40) by tracing the marginal rays (which pass through the edge of the exit pupil) through the front lens element (32) (Box 88).

25

6. Repeat steps 1 to 5 (Boxes 80 to 90 - via Box 92) until the aperture stop has a smaller diameter than the exit pupil and the marginal ray height as it is traced through the front lens element is lower than at the exit pupil. Then fix the above defined parameters (Box 96 - via Box 94).

30

7. Define the diameters of the remaining lens elements of the compound lens to be less than the diameter of the front lens element (32) (Box 98).

5 8. Define the function of the compound lens, for example in the Figure 2 example, the compound lens (30) is defined as a finite conjugate lens with specified object and image distances (Box 100) and design remainder of compound lens using Code V software (Box 102) without
10 altering the relationship between the exit pupil and the marginal ray height through the front lens element.

Examples of two further compound lenses in accordance with the present invention and designed in accordance with the above method
15 are shown in Figures 5 and 6.

The compound lens (60) shown in Figure 5 comprises four lens elements (62,64,66,68) comprising eight lens surfaces (a to h). The lens element (62) is the front lens element and faces towards the screen
20 (8a) or field lens (8b) in the arrangements of Figures 1a and 1b respectively. The front lens element (62) is made of SF57 SCHOTT glass and has a front surface (a) with a radius of curvature of 10.00mm and a rear surface (b) with a radius of curvature 13.78mm and a thickness along its optical axis (42) of 1.45mm. It should be noted that
25 the principle ray (44) crosses the optical axis (42) of the compound lens (60) at the rear surface (b) of the front lens element (62) and so the aperture stop of the compound lens (60) lies in the plane (40) perpendicular to the optical axis (42) and which intersects the optical axis (42) at said rear surface (b). A second lens element (64) is located
30 behind the rear surface (b) of the front lens element (62) at a distance along the optical axis (42) of the lens elements of 0.30mm. The second lens element (64) is made of SSK2 SCHOTT glass and has a front

surface (c) with a radius of curvature 10.16mm and a rear surface (d) with a radius of curvature -30.65mm and a thickness along its optical axis (42) of 3.11mm. A third lens element (66) is located behind the rear surface (d) of the second lens element (64) at a distance along the optical axis (42) of the lens elements of 0.34mm. The third lens element (66) is made of SF59 SCHOTT glass and has a front surface (e) with a radius of curvature -24.66mm and a rear surface (f) with a radius of curvature of 7.21mm and a thickness along its optical axis (42) of 4.07mm. A rear lens element (68) made of SF59 SCHOTT glass is located behind the rear surface (f) of the third lens element (66) at a distance along the optical axis (42) of the lens elements of 1.46mm. The rear lens element (68) has a front surface (g) with a radius of curvature of 16.10mm and a rear surface (h) with a radius of curvature of -51.68mm and a thickness along its optical axis (42) of 1.14mm.

The exit pupil of the compound lens (60) is located in the plane (46) shown in dotted lines in Figure 5 and is bounded by the circumference of the front surface (a) of the front lens element (62).

The compound lens (70) shown in Figure 6 comprises four lens elements (72,74,76,78) comprising eight lens surfaces (a to h). The lens element (72) is the front lens element and faces towards the screen (8a) or field lens (8b) in the arrangements of Figures 1a and 1b respectively. The front lens element (72) is made of SF57 SCHOTT glass and has a front surface (a) with a radius of curvature of 10.00mm and a rear surface (b) with a radius of curvature 13.78mm and a thickness along its optical axis (42) of 1.45mm. It should be noted that the principle ray (44) crosses the optical axis (42) of the compound lens (70) at the rear surface (b) of the front lens element (72) and so the aperture stop of the compound lens (70) lies in the plane (40) perpendicular to the optical axis (42) and which intersects the optical axis (42) at said rear surface (b). A second lens element (74) abuts the

rear surface (b) of the front lens element (62). The second lens element (74) is made of SSK2 SCHOTT glass and has a front surface (c) with a radius of curvature 9.56mm and a rear surface (d) with a radius of curvature -37.45mm and a thickness along its optical axis (42) of 1.72mm. A third lens element (76) is located behind the rear surface (d) of the second lens element (74) at a distance along the optical axis (42) of the lens elements of 0.93mm. The third lens element (73) is made of SF58 SCHOTT glass and has a front surface (e) with a radius of curvature -22.30mm and a rear surface (f) with a radius of curvature of 7.44mm and a thickness along its optical axis (42) of 4.23mm. A rear lens element (78) made of SF58 SCHOTT glass is located behind the rear surface (f) of the third lens element (76) at a distance along the optical axis (42) of the lens elements of 0.50mm. The rear lens element (78) has a front surface (g) with a radius of curvature of 22.46mm and a rear surface (h) with a radius of curvature of -28.64mm and a thickness along its optical axis (42) of 4.60mm.

The exit pupil of the compound lens (70) is located in the plane (46) shown in dotted lines in Figure 6 and is bounded by the circumference of the front surface (a) of the front lens element (62).

Claims

1. A compound lens arrangement for use in an array of such lens
5 arrangements comprising at least two lens elements including a front
lens element having a front lens surface which is the largest diameter
lens surface in the compound lens arrangement, wherein the exit pupil
of the compound lens arrangement lies in the plane of and is bounded
by the edge of said front lens surface.
10
2. A compound lens arrangement according to claim 1 wherein the
aperture stop of the lens arrangement lies in front of the lens elements
of the compound lens arrangement other than the front lens element.
- 15 3. A compound lens arrangement according to claim 1 wherein the front
lens element has a rear lens surface and the aperture stop of the
compound lens arrangement lies in a plane which intersects the optical
axis of the compound lens arrangement at the rear lens surface.
- 20 4. A compound lens arrangement according to any one of the
preceding claims wherein the front lens element is a compound lens.
5. A compound lens arrangement according to any one of claims 1 to 3
wherein the front lens element is a single lens.
25
6. A compound lens arrangement according to any one of the
preceding claims wherein the front lens element is the largest diameter
lens element in the compound lens arrangement.
- 30 7. A compound lens arrangement according to the present invention
wherein a rear lens surface of the front lens element is concave.

8. A compound lens according to any one of the preceding claims wherein the front lens surface of the front lens element is convex.

9. A compound lens arrangement substantially as hereinbefore
5 described with reference to any one of the accompanying Figures.

10. A projector for use in an array of such projectors comprising a compound lens arrangement according to any one of the preceding claims.

10

11. A projector substantially as hereinbefore described with reference to any one of the accompanying Figures.

12. An autostereo projection system comprising an array of projectors
15 according to claim 10.

13. An autostereo projection system substantially as hereinbefore described with reference to any one of the accompanying Figures.

20 14. A method of designing a compound lens arrangement for use in an array of such lenses comprising the steps of;

25

defining the material of a front lens element of the compound lens arrangement, the diameter of a front lens surface of the front lens element, the radius of curvature of a front lens surface and a rear lens surface of the front lens element and defining the location of an exit pupil of the compound lens arrangement to be in the plane of and bounded by the edge of said front lens surface,

30

based on the above defined parameters, tracing the location and magnitude of an aperture stop of the

compound lens arrangement by tracing the marginal ray height through the front lens element using ray tracing means,

5 repeating the above steps until the marginal ray height traced through the front lens element is highest at the exit pupil and then fixing the above defined parameters,

10 defining the diameters of the remaining lens surfaces of the compound lens arrangement to be less than that of the front lens surface of the front lens element and defining the functionality of the compound lens arrangement, and

15 using ray tracing means to design the remainder of the compound lens arrangement in such a way that the remaining lens surfaces do not alter the relationship between the exit pupil and the marginal ray height through the front lens element as defined above.

20 15. A method according to claim 14 wherein the parameters defined in the first step of the method are only fixed when the diameter of the aperture stop is less than the diameter of the exit pupil.

25 16. A method according to claim 14 or 15 wherein the step of defining the diameter of the front lens surface of the front lens element comprises the step of defining the diameter of the front lens element.

30 17. A method according to any one of claims 14 to 16 wherein the step of defining the functionality of the compound lens arrangement comprises the step of defining the compound lens arrangement as a finite conjugate lens with specified object and image distances.

18. A method substantially as hereinbefore described with reference to any one of the accompanying Figures.

ABSTRACT**Compound Lens Arrangement for use in Lens Arrays**

5 A compound lens arrangement for use in an array of such lens
arrangements comprising at least two lens elements including a front
lens element having a front lens surface which is the largest diameter
lens surface in the compound lens arrangement, wherein the exit pupil
10 of the compound lens lies in the plane of and is bounded by the edge of
said front lens surface. This enables the compound lens arrangements
in an array to abut. The invention particularly relates to compound lens
arrangements for use in projectors which projectors are used in an array
in an autostereo projection system and allows adjacent projectors to
abut.
